

Subway Screen Project

Project Description

The mayor of the city X has decided to update the screens on their subway trains as it is something like this.

After seeing the screens in the stations of the city Calgary, he wants a similar system to be implemented . Your task is to create a Java17 desktop application that displays information on the screens inside the trains. Something similar to the following figure but with some improvements:

The city X has three subway lines (Red, Green, and Blue) with approximately 120 stations. A list of the stations has been provided by the city hall in the form of a CSV file (i.e., [Map](#)).

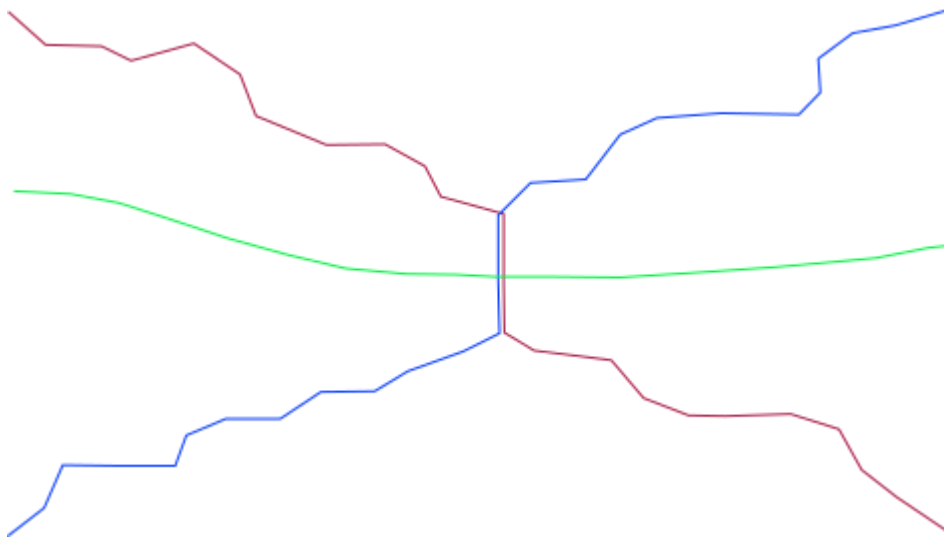

A controlling system reports the position and direction of the 12 trains every 15 seconds. Each line has four trains that travel continuously on their respective line. To access the data of the controlling system, a simulator is provided in the form of a jar file. The simulator places a file in the form of `Train_<Timestamp>.CSV` in any

output folder specified via command line. To run the simulator and see the generated outputs, please follow the instructions provided in the simulator's [readme file](#).

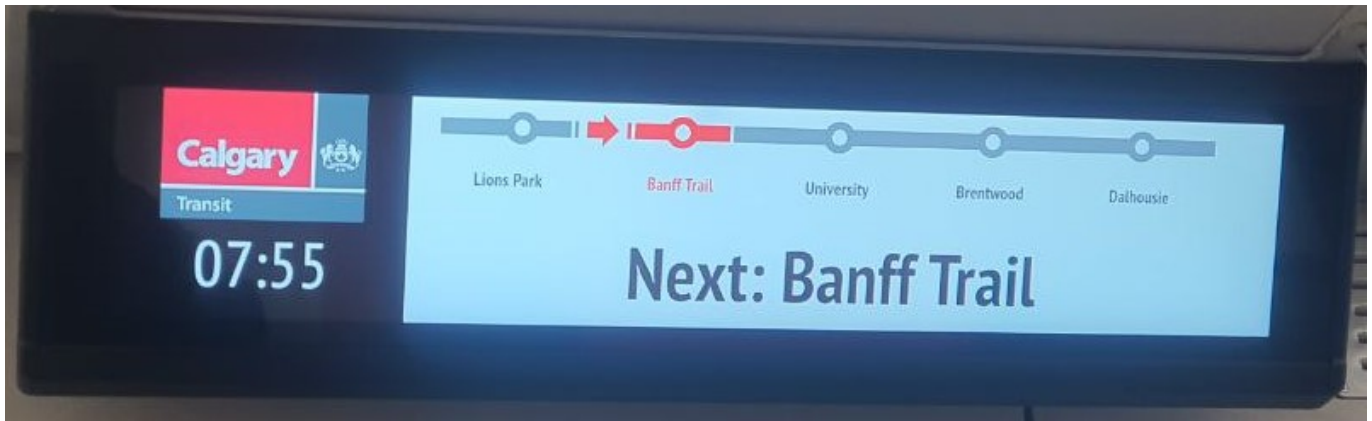

Three sample Java applications have been developed to run the jar file. Please fork the repository provided at <https://github.com/mjza/SubwayScreen> and continue your development on your forked repo. Make your fork hidden. Please note that the amount of your contribution is measured by the amount of commits/contributes that you make in your repository.

Your application must have the following functionalities:

1. The main screen is divided to four sections.
2. The largest section will display advertisements. Please create a database and design tables to moderate text and media of the advertisements that the city hall absorbs and displays on the screen. The advertisements must be changed continuously. Each ad must be shown for 10 seconds each. Every 10 seconds, display the big map for 5 seconds in the advertisement frame. The map must show the position of the trains including the current train. I made several pictures in the [Map folder](#).

3. A section for time and weather report must be included in the right or left corner. Please use the website <https://openweathermap.org/> to download the simple HTML page and parse it using regular expressions to extract the data. This task must be done in a separated jar file and you use it in your code as external library. You need to develop a separated Java project for it. Represent the weather report in any way you like, but please note that only the daily report is required, not the forecast for the next days. The website provides weather for different cities using a code. For example, for Calgary use <https://openweathermap.org/city/5913490>. Please collect the codes for 10 cities and set the city name via command line.
4. A section for news must be included. Use a free open API like <https://newscatcherapi.com/> to access news data.
5. Finally, a section must be included that shows the two past and three future train stations and displays the direction of the train. Something like this:

Note that the layout of the screens does not need to be exactly like the provided figures, but it should have similar functionalities.

A UML class diagram is required to demonstrate the following components in your code:

1. Inheritance
2. Abstract classes/Interfaces
3. Polymorphism
4. Usage of Static/Final/Final Static
5. Composition, Aggregation, and Association relationships
6. Usage of the "uses" and "throws" relationships for error handling
7. Definition of Cardinalities.

Please note you must demonstrate that you have the ability to use OOP paradigm in solving problems.

Good luck with your project!
